Diagnosing the Subscriber Retention Gap

Data Exploration • Problem Identification • Recommendations

Prepared by Biswa

Product Analyst Assignment — PeakPulse (Recovery, Strain & Sleep Wearable)

Retention collapses in the first 30 days — well short of the 85% goal

56.8%

Actual D30 retention, vs. an 85% renewal target — a 28-point gap

74%

of ALL churn happens within the first 30 days — the dominant churn window (median cancellation: day 25)

Users survive the first week fine (98% D7) — the drop-off is concentrated right around the first renewal charge, not at signup.

App engagement predicts retention — health scores and community features don't

+85%

more app opens among retained users — the single strongest behavioral signal we found (correlation $r = 0.29$)

Near-zero correlation with retention

Avg. recovery score	$r = -0.01$
Avg. sleep score	$r = 0.01$
Avg. strain score	$r = -0.02$
Device-active minutes/day	$r = -0.02$
Team / community membership	42.7% vs 41.8% retained — no lift
Journaling frequency	$r = 0.02$

Users are wearing the device and generating health data either way — what separates retained from churned users is whether they come back into the app.

Longer commitment plans churn hardest — and the gap is worth ~\$690K/yr

\$893,820/yr

in recurring revenue forfeited from subscribers who have already churned

\$691,000/yr

estimated revenue opportunity from closing the gap between today's 41.8% renewal rate and the 85% target (~2,159 additional retained subscribers)

\$697,740/yr

of that forfeited revenue comes from users who churned within 30 days — the single highest-leverage window

Three data-backed recommendations

1

Fix the Day 8–30 cliff

Build a proactive first-billing-cycle journey: reminder of value earned so far, a personal recovery/sleep recap, and a save offer just before the day-25–30 renewal window, since 74% of churn and \$698K/yr in lost revenue concentrate right there.

2

Re-engage app opens, not just device wear

Users keep wearing the device after they stop opening the app. Ship a weekly insight digest, streaks, and win-back push notifications targeting lapsed openers — app-open frequency is the strongest predictor of retention we found ($r = 0.29$).

3

Investigate the annual/biannual mismatch

Annual and biannual subscribers churn 2–3x more than monthly ones — the opposite of the usual pattern. Run exit interviews with this segment and consider a monthly-first funnel with an opt-in upgrade once engagement is proven.

How we'd measure success

Recommendation	Primary metric	Target
Fix Day 8–30 cliff	D30 subscriber retention rate	56.8% → 75%+ within 2 quarters
Re-engage app opens	% of subscribers opening app $\geq 2x$ /week in first 30 days	Baseline → +20 pts
Annual/biannual mismatch	D30 retention, annual & biannual cohorts specifically	23% avg → 45%+

Also track weekly cohort retention curves (not just a point-in-time rate), and A/B test onboarding-week nudges against a holdout group before full rollout.

Assumptions & methodology

- “Retained” = `subscription.is_canceled = False` as of the data snapshot (latest `subscription_start_date`: 2023-06-08). No separate free tier exists in the data, so Part 1’s “free → premium” funnel was reinterpreted as onboarding completion → active subscriber.
- Plan pricing terms aren’t stored explicitly. `subscription_end_date` is only populated for monthly plans; annual/biannual term length was assumed (annual = 12-month term at \$300/yr, biannual = 24-month term at \$240) based on relative pricing — stated here as an explicit assumption, not a verified fact.
- Onboarding funnel approximated from proxy events: account creation (`users.csv`) → first app session → `calibration_complete` flag → first `daily_score` → currently active.
- Anomaly noted, not yet explained: cancellations spike sharply in the final 2 weeks of the data window (422 and 335/week) while new subscriptions had nearly stopped — could reflect a real event, or a data-export/cutoff artifact. Flagged for follow-up with engineering before acting on it.
- Cancellation reasons are close to evenly distributed across categories (10–12% each) and didn’t meaningfully differ by plan type — treated as a weak signal versus the timing and engagement patterns above.
